Abstract

This paper investigates the following question: Given a grid ϕ, where ϕ is a proper subset of the integer 2D or 3D grid, which graphs admit straight-line crossing-free drawings with vertices located at (integral) grid points of ϕ? We characterize the trees that can be drawn on a strip, i.e., on a two-dimensional $n \times 2$ grid. For arbitrary graphs we prove lower bounds for the height $k$ of an $n \times k$ grid required for a drawing of the graph. Motivated by the results on the plane we investigate restrictions of the integer grid in 3D and show that every outerplanar graph with $n$ vertices can be drawn crossing-free with straight lines in linear volume on a grid called a prism. This prism consists of $3n$ integer grid points and is universal – it supports all outerplanar graphs of $n$ vertices. We also show that there exist planar graphs that cannot be drawn on the prism and that extension to an $n \times 2 \times 2$ integer grid, called a box, does not admit the entire class of planar graphs.

1 Introduction

This paper deals with crossing-free straight-line drawings of planar graphs in two and three dimensions. Given a graph $G$, we constrain the vertices in a drawing of $G$ to be located at integer grid points and aim at computing drawings whose area/volume is small. The interest in these two requirements is motivated in part by the fact that the screen of a computer is an integer grid of limited size and by the fact that a drawing algorithm should not be affected by round-off errors when representing the output coordinates. Also, the increasing demand of visualization algorithms to draw and browse very large networks makes it natural to study what families of graphs can be entirely visualized on a two-dimensional screen and to investigate how much benefit can be obtained from the third dimension to represent the overall structure of a huge graph in a small portion of a virtual 3D environment. A rich body of literature has been published on computing straight-line drawings of graphs, such that the vertices are the intersection points of an integer 2D grid and the overall area of the drawing is kept small. Typically, papers that deal with this subject focus on lower bounds on the area required by straight-line drawings of specific classes of graphs and on the design of algorithms that possibly match these lower bounds. A very limited list of milestone papers in this field includes the works by de Fraysseix, Pach, and Pollack [11, 12] and by Schnyder [38] who independently showed that every $n$-vertex triangulated planar graph has a crossing-free straight-line drawing such that the vertices are at grid points, the size of the grid is $O(n) \times O(n)$, and that this is worst case optimal; the work by Kant [26, 27], Chrobak and Kant [8], Schnyder and Trotter [39], Felsner [21] and Chrobak, Goodrich, and Tamassia [7] who studied convex grid drawings of triconnected planar graphs in an integer grid of quadratic area, and the many papers proving that linear or almost-linear area bounds can be achieved for classes of trees, including the result by Garg, Goodrich and Tamassia [23] and the result by Chan [5]. Summarizing tables and more references can be found in the book by Di Battista, Eades, Tamassia, and Tollis [14].

While the problem of computing small-sized crossing-free straight-line drawings in the plane has a long tradition, its 3D counterpart has become the subject of much attention only in recent years. Chrobak, Goodrich, and Tamassia [7] gave an algorithm for constructing 3D convex drawings of triconnected planar graphs with $O(n)$ volume and non-integer coordinates. Cohen, Eades, Lin and Ruskey [9] showed that every graph admits a straight-line crossing-free 3D drawing on an integer grid of $O(n^3)$ volume, and proved that this is asymptotically optimum. Calamoneri and Sterbini [3] showed that all 2-, 3-, and 4-colourable graphs can be drawn in a 3D grid of $\tilde{O}(n^2)$ volume with $O(n)$ aspect ratio and proved a lower bound of $\Omega(n^{1.5})$ on the volume of such graphs. For r-colourable graphs, Pach, Thiele and Tóth [31] showed a bound of $\tilde{O}(n^2)$ on the volume. Garg, Tamassia, and Vocca [24] showed that all 4-colorable graphs (and hence all planar graphs) can be drawn in $O(n^{1.5})$ volume and with $O(1)$ aspect ratio but using a grid model where the coordinates of the vertices may not be integer. In this paper we study the problem of computing drawings of graphs on integer
2D or 3D grids that have small area/volume. The area/volume of a drawing $\Gamma$ is measured as the number of grid points contained in or on a bounding box of $\Gamma$, i.e., the smallest axis-aligned box enclosing $\Gamma$. Note that along each side of the bounding box the number of grid points is one more than the actual length of the side. We approach the drawing problem with the following point of view: Instead of “squeezing” a drawing onto a small portion of a grid of unbounded dimensions, we assume that a grid of specified dimensions (involving a function of $n$) is given and we consider what the graphs are whose drawings fit that restricted grid. For example, it is well-known that there are families of graphs that require $\Omega(n^2)$ area to be drawn in the plane, the canonical example being a sequence of $n/3$ nested triangles (see [12, 8, 38]). Such graphs can be drawn on the surface of a three dimensional triangular prism of linear volume and using integer coordinates. Thus a natural question is whether there exist specific restrictions of the 3D integer grid of linear volume that can support straight-line crossing-free drawings of meaningful families of graphs. For planar graphs the best known results for three dimensional crossing-free straight-line drawings on an integer grid are by Calamoneri and Sterbini [3] who show $O(n^3)$ volume for general planar graphs and by Eades, Lin and Ruskey [9] who show $O(n \log n)$ volume for trees.

The main contributions of the present paper are investigations concerning the drawability of graphs on 2D and 3D restricted integer grids and new drawing algorithms for some classes of graphs. An overview of the results is as follows.

- We characterize those trees that can be drawn on a strip, i.e., an integer 2D grid restricted to two consecutive horizontal grid lines. From the characterization we derive a linear time algorithm to generate such drawings, if possible. This result was independently obtained by Schank [36] in his Master’s thesis.

- Generalizing the result for strips, we present a lower bound “the strictness of a tree” for the number $k$ of horizontal grid lines required for grid drawings of trees. A consequence of this bound is that for any given $k$ there always exist some trees that are not drawable on the $n \times k$ grid.

- We show that the strictness of a tree is closely related to the well-known parameter path-width. For general graphs the path-width is shown to be a lower bound for the height of grid drawings.

- Motivated by the results on restricted integer 2D grids we explore the capability of restricted 3D integer grids for supporting linear volume drawings of graphs. In particular, we focus on two types of 3D integer grids to be defined subsequently, both having linear volume, called the prism and the box. We show that all outerplanar graphs can be drawn in linear volume on a prism. Note that this is the first result on 3D straight-line drawings of a significant class of planar graphs that achieves linear volume with integer coordinates.
• We further explore the class of graphs that can be drawn on a prism by asking whether the prism is a universal 3D integer grid for all planar graphs. We answer this question in the negative by exhibiting examples of planar graphs that cannot be drawn on a prism. We also investigate the relationship between prism-drawable and Hamiltonian graphs.

• We extend our study to box-drawability and present a characterization of the box-drawable graphs. While the box would appear to be a much more powerful grid than the prism, we prove that not all planar graphs are box-drawable.

Several recent related results about 3D straight line drawings of limited volume have been published after the conference version of this paper was presented at the Symposium on Graph Drawing GD 2001 [22]. Dujmovic, Morin, and Wood [20] present \( O(n \log^2 n) \) volume drawings of graphs with bounded tree-width and \( O(n) \) volume for graphs with bounded path-width. Wood [42] shows that also graphs with bounded queue number have 3D straight-line grid drawings of \( O(n) \) volume. A very recent result by Dujmovic and Wood [17] shows that linear volume can also be achieved for graphs with bounded tree-width; they show 3D straight-line grid drawings of volume \( c \times n \) for these graphs, where \( c \) is a constant whose value exponentially depends on the tree-width. Di Giacomo, Liotta, and Wismath [16] show \( 4 \times n \) volume for a subclass of series-parallel graphs. The problem of computing straight-line 3D drawings of planar graphs on an integer grid of \( o(n^2) \) volume is still open. A recent lower bound on the volume of 3D straight line drawings as a function of the number of edges is obtained by Bose, Czyzowicz, Morin, and Wood [2].

The remainder of the paper is organized as follows. Preliminaries and basic definitions are in Section 2. The study of trees drawable on restricted integer 2D grids is the topic of Section 3. In this section we also investigate the connection of grid drawings and path-width. Section 4 presents the linear volume algorithm for outerplanar graphs. Combinatorial properties of the graphs that can be drawn on the surface of a prism and on a box are studied in Sections 5 and 6. Final remarks, directions for further research and open problems can be found in Section 7.

## 2 Preliminaries

We assume familiarity with basic graph drawing and computational geometry terminology; see for example [33, 14]. Since in the remainder of the paper we shall only study crossing-free straight-line drawings of planar graphs, from now on we shall simply talk about “graphs” to mean “planar graphs” and about “drawings” to mean “crossing-free straight-line drawings”. We use the terms “vertex” and “edge” for both the graph and its drawing. We will draw graphs such that vertices are located at integer grid points. The dimensions of a grid are specified as the number of different grid points along each side of a bounding box of the grid. In two dimensions, a \( p \times q \) grid consists of all points \((i, j)\) with

\( i \leq p \) and \( j \leq q \).
$1 \leq i \leq p$ and $1 \leq j \leq q$ that have integer coordinates. In three dimensions, a $p \times q \times r$ grid consists of all points $(i, j, k)$ with $1 \leq i \leq p$, $1 \leq j \leq q$ and $1 \leq k \leq r$ that have integer coordinates; $p$, $q$ and $r$ are referred to as the $x$-, $y$-, and $z$-dimension of the grid, respectively.

We shall deal with the following grids and drawings.

- A 2D 1-track (or simply a track) is an $\infty \times 1$ grid; a 1-track drawing of a graph $G$ is a drawing of $G$ where the vertices are at distinct grid points of the track.

- A 2D strip is an $\infty \times 2$ grid; note that a strip contains two tracks. A strip drawing of a graph $G$ is a drawing of $G$ with the vertices located at distinct grid points of the strip and the edges either connect vertices on the same track or connect vertices on different tracks.

- Next we extend the notion of a strip to multiple overlapping strips. Let $k$ be a given positive integer value. A 2D $k$-track grid is an $\infty \times k$ grid consisting of $k$ consecutive parallel tracks. A $k$-track drawing of a graph $G$ is a drawing of $G$ where the vertices are at distinct grid points of the $k$-track and edges are only permitted between vertices that are either on the same track or that are one unit apart in their $y$-coordinates. Note that the previous two grids are the specific cases of $k = 1$ and $k = 2$.

- Let $k$ be a given positive integer value. In an $n \times k$-grid drawing of a graph $G$, the vertices are located at distinct grid points and the edges may connect any pair of vertices on that grid. To avoid confusion with track drawings, we refer to the value $k$ as the number of grid lines in the grid drawing.

- We will also study two different types of $n \times 2 \times 2$ grids. A box is an $n \times 2 \times 2$ grid where each side of the bounding box is also a grid line. Therefore, a box has four tracks which lie on two parallel planes and are one grid unit apart from each other. A prism is a subset of an $n \times 2 \times 2$ grid obtained by removing a track from a box. Figure 1 shows an example of a box of size $6 \times 2 \times 2$ and an example of a prism.

![Figure 1: A box and a prism](image-url)

Note that $k$-track drawings differ from the so-called $k$-level drawings (see, e.g., [25]) as in a $k$-track drawing (consecutive) vertices on the same track are permitted to be joined by an edge and the given graph is undirected. Let $\phi$ be one
of the grids defined above. We say that a graph \( G \) is \( \phi \) drawable if \( G \) admits a \( \phi \) drawing \( \Gamma \) where each vertex is mapped to a distinct grid point of \( \phi \).

**Property 1** A graph is 1-track drawable if and only if it is a forest whose vertices have degree at most two.

While in a \( k \)-track drawing no edge can connect vertices that are on non-consecutive tracks, in an \( n \times k \)-grid this is allowed. As the following property shows, this difference has immediate consequences on the families of \( k \)-track drawable and \( n \times k \)-grid drawable graphs.

**Property 2** Let \( k \geq 3 \) be a fixed positive integer. There exist graphs with \( n \) vertices that are \( n \times k \)-grid drawable but are not \( k \)-track drawable.

**Proof.** The graph \( K_4 \) has an \( n \times 3 \)-grid drawing but it does not have a 3-track drawing. Indeed \( K_4 \) is not drawable on tracks. Furthermore any graph containing \( K_4 \) as a subgraph is not track-drawable. Given a drawing of a graph on an \( n \times k \)-grid (for \( k > 3 \)), we can attach a copy of \( K_4 \) which makes the resulting graph not track-drawable. \( \square \)

In the extended abstract for the graph drawing conference GD'01[22] we incorrectly argued that for trees \( n \times k \)-grid drawable is equivalent to \( k \)-track drawable. It was first observed by Matthew Suderman that this was false. In a recent manuscript Suderman [40] describes a family \( S^k \) of trees, such that \( S^k \) can be drawn on the \( n \times (k + 1) \) grid but requires \( 2k - 1 \) tracks. Suderman's results are actually stated in terms of the pathwidth \( pw \) of a tree (a notion introduced in the next section). He shows that \( pw(S^k) = k \) and every tree \( T \) with \( pw(T) \leq k \) admits a drawing on \( 2k - 1 \) tracks.

### 3 Grids, Path-width and Trees

In this section we investigate the connections between drawability of a graph \( G \) on grids and the path-width of \( G \). The notion of the path-width of a graph \( G \) was introduced by Robertson and Seymour[34] in the first paper of their series on graph minors. A path decomposition of a graph \( G = (V, E) \) is a sequence \( W_1, W_2, \ldots, W_t \) of subsets of \( V \) such that

- \( \forall (u, v) \in E \) there exists \( i \) such that \( u, v \in W_i \)
- \( \forall v \in V \) the set \( I(v) = \{ i : v \in W_i \} \) is an interval of \( \{1, \ldots, t\} \), i.e. if \( a < b < c \) and \( a, c \in I(v) \) then \( b \in I(v) \).

The width of the path decomposition is \( \max(|W_i| - 1 : i = 1, \ldots, t) \) and the path-width of \( G \), denoted \( pw(G) \) is the minimum width of a path decomposition of \( G \). The path-width of an independent set is defined as zero.

Several graph parameters have been shown to be equivalent to path-width. The interval thickness \( \Theta(G) \) is the smallest max-clique over all interval supergraphs of \( G \). Since interval graphs are perfect this can also be stated in terms
of the chromatic number: \( \Theta(G) = \min \{ \chi(H) : H \text{ is an interval graph with } E(G) \subseteq E(H) \} \). Möhring [30] has shown that \( \Theta(G) = \text{pw}(G) + 1 \). In node searching, an undirected graph is considered as a system of tunnels in which a fugitive is hidden. The node search number \( \text{ns}(G) \) is the least number of searchers required to capture the fugitive when the search is governed by the following rules: A search move consists of placing a searcher at a node or removing a searcher from a node. The fugitive is captured if both ends of the edge where he hides are simultaneously occupied by a searcher. The fugitive is allowed to move (at any speed) along edges subject to the condition that he never passes a node occupied by a searcher. Kirousis and Papadimitriou [28] have shown that \( \Theta(G) = \text{ns}(G) \). Moreover there is an optimal search, i.e., a search requiring only \( \text{ns}(G) \) searchers, such that after an edge has been cleared by two searchers simultaneously guarding its end-nodes it never recontaminates, i.e., there never appears a path that carries no searcher connecting the cleared edge with a contaminated (uncleared) one.

We now show that the path-width is a lower bound on the number \( k \) of grid lines needed for an \( n \times k \) grid drawing for general planar graphs. We note that a similar result was obtained in [19] however in the context of \( h \)-layer graph drawings.

**Theorem 1** Let \( G \) be a planar graph. Then 
\[
\text{pw}(G) \leq \min_{k} (G \text{ is drawable on an } n \times k \text{ grid}).
\]

**Proof.** We prove the inequality in the node searching context; recall \( \text{ns}(G) = \text{pw}(G) + 1 \). Given a planar graph \( G \) which is drawn on an \( n \times k \) grid, we show that the layout can be used to design a node search strategy using \( k+1 \) searchers for \( G \). At the beginning a grid-line-searcher is placed on the leftmost node of each of the \( k \) grid lines of the drawing. The invariant is that at any intermediate step of the search there is a searcher on each grid line and the \( k \) nodes occupied by these searchers form a node separator. Left of the searchers there are cleared edges and nodes; edges and nodes to the right are not yet cleared and there is no edge connecting a cleared with an uncleared node. A move consists of identifying a searcher \( s \) sitting on a node \( v(s) \) on grid line \( t(s) \), such that either there is no edge connecting \( v(s) \) to an uncleared node or there is exactly one such edge and this edge connects \( v(s) \) to the next node right of \( v(s) \) on the same grid line. In both cases the \( (k+1) \)st searcher \( s' \) is placed on the next grid line \( v' \) on the same grid line \( t(s) \). Then \( s \) moves to \( v' \) thus setting \( s' \) free again. We claim that a move as described is possible as long as not all the \( k \) grid-line-searchers are sitting on the rightmost node of their line. Since a move clearly keeps the invariant valid the claim implies that the graph can be decontaminated from left to right in a sequence of moves. It remains to prove the existence of a move. Label the grid lines \( t_1, t_2, \ldots, t_k \) from lowermost to topmost. Denote the node occupied by the grid-line-searcher on \( t_i \) by \( v_i \). With \( v_i \) associate the number \( h_i \) of the highest grid line such that there is an uncleared edge from \( v_i \) to a node on grid line \( h_i \); if there is no uncleared edge leaving \( v_i \) we set \( h_i = 0 \). Since \( h_k \leq k \) there is a least index \( i \) such that \( h_i \leq i \). We claim that we can choose
the searcher of grid line \( t_i \) for the move. If \( i = 1 \) condition \( h_1 \leq 1 \) implies that we can advance the searcher on the first grid line. If \( i > 1 \) consider the edge emanating from node \( v_{i-1} \) to a node on grid line \( h_{i-1} \geq i \). By planarity and since \( h_{i-1} \geq i \) this edge shields \( v_i \) from all uncleared nodes on grid lines \( t_j \) for \( j < i \). Therefore, there can be at most one edge leaving \( v_i \) to an uncleared node to the right and this node must sit on the same grid line.

For the case of trees Suderman [40] has given tight bounds for the gap between path-width and the required height of the grid. Depending on the drawing model chosen, this height is bounded by the \( \beta \) fold of the path-width with \( \beta \in \{ \frac{1}{2}, 2, 3 \} \).

In contrast to the situation with trees, the gap in the inequality of Theorem 1 can be arbitrarily large for other classes of planar graphs. Let \( G_k \) be the graph consisting of \( 2k \) nested triangles (see Figure 2 for the case \( k = 3 \)). It is not difficult to see that a grid drawing of \( G_k \) requires at least \( 2k \) grid lines (i.e. an \( n \times 2k \) grid). Namely, since \( G_k \) is three-connected it is enough to study the drawings given by all choices of outer faces. If the outer face is a three-cycle, by induction we have that a drawing of \( G_k \) requires a number of grid lines that is at least twice the number of nested triangles, i.e. it requires at least \( 4k \) grid lines. If the outer face is a four cycle, we still have to draw a three cycle with at least \( k \) nested triangles inside, and therefore at least \( 2k \) grid lines are required. However, the node-search number of \( G_k \) is 4, independent of \( k \). In an optimal search the searchers sweep the triangles starting at the innermost and moving

\[ \text{Figure 2: Six nested triangles.} \]

\[ \text{Figure 3: A drawing of } G_3 \text{ on an } n \times 6 \text{ grid.} \]
out. An optimal drawing for $G_3$ is given in Figure 3.

3.1 Minor monotone issues

The contraction of an edge $e = (x, y)$ in a graph means replacing $x$ and $y$ by a single vertex $z$ which is made adjacent to all the remaining neighbors of $x$ and $y.$

Given a graph $G$ we can generate smaller graphs by repeatedly deleting and contracting edges and deleting isolated vertices. These smaller graphs are called minors of $G.$ Define $G' \prec G$ if $G'$ is a minor of $G.$ The relation $\prec$ is an order relation on the set of all graphs. A set $\mathcal{P}$ of graphs is minor monotone if $G \in \mathcal{P}$ and $G' \prec G$ implies $G' \in \mathcal{P}.$

Important examples of minor monotone sets of graphs are: forests, outerplanar graphs, planar graphs and for any fixed $k$, the set of graphs $G$ with $pw(G) \leq k.$ A fundamental result of Robertson and Seymour [35] asserts that every minor monotone set of graphs $M$ is characterized by a finite set of obstructions, i.e. there is an integer $t$ and a list of graphs $O_1, O_2, \ldots, O_t$ such that $G \in M$ iff $O_i \not\prec G$ for $i = 1, \ldots, t.$ A classical instance is the theorem of Wagner [41]: $G$ is planar iff it has no minor isomorphic to $K_5$ or $K_{3,3}.$

From Theorem 1 it is conceivable to view the minimal height $k$ such that a planar graph admits a drawing on an $n \times k$ grid as a more discriminating, i.e. refined, version of path-width. The following theorem shows that this parameter ‘grid-height’ lacks one very important property.

**Theorem 2** Beingdrawable on an $n \times k$ grid is not a minor monotone graph property for $k \geq 3.$

**Proof.** The graph $G$ shown in Figure 4 is drawn on three grid lines. By contracting the dotted edge we obtain the graph $G'$ shown to the left in Figure 5. We show that $G'$ requires a grid of height at least four.

In Figure 5 the vertex resulting from the contraction is emphasized and labeled $c,$ another vertex of degree two is labeled $t.$ Let $G'_t$ be the graph obtained by deleting $t.$

The first step of the proof is to show that in every drawing of $G'_t$ the bold vertices are drawn on the middle line. This is based on an observation which is interesting in its own right.
Let $G$ be embedded on a grid of height $k$ and let $C$ be the outer cycle of $G$. The interior vertices of $G$, i.e., those not on $C$, are embedded on the grid lines from 2 to $k - 1$.

For the case of three grid lines, $k = 3$, this implies that all vertices not on the outer cycle must be drawn on the middle grid line. As a consequence, the graph induced by the inner vertices must be a subgraph of a path.

In the case of $G'_t$, there are two candidates for the outer cycle namely, the one shown in the figure and the cycle of length four including the edge $(s, c)$. In both cases the four black vertices are interior and must be drawn on the middle grid line. Assume that $s$ is placed on grid line 1; then both vertices $a$ and $c$ have to go on grid line 3. A drawing of $G'$ contains a drawing of $G'_t$, hence, for a drawing of $G'$ on a grid of height three we also have: If $s$ is on line 1 then $a$ and $c$ are on line 3. However, since $x$ and $t$ are common neighbours of $a$ and $c$ this placement of $a$ and $c$ makes a crossing of edges unavoidable. In conclusion the minor $G'$ of $G$ has no drawing on a grid of height 3.

An interesting open problem suggested by one of the referees is whether for trees and forests the required height for grid drawings might be a minor monotone parameter.

### 3.2 Drawings of Trees

Next we consider drawings of trees. As a first step we characterize the family of strip-drawable trees and give linear time recognition and drawing algorithms for such trees.

The approach taken applies to strip-drawable trees and has a natural generalization which leads to the notion of a $k$-strict tree. We show that a $(k+1)$-strict tree cannot be drawn on an $n \times k$ grid. We then show that the strictness of a tree is closely related to the path-width. More precisely, there is a difference of at most one between the two parameters. In his recent paper Mathew Suderman [40] has obtained tight bounds on the height of a grid required for drawings of trees of path-width $k$ in several drawing models.
3.2.1 Strip-Drawable Trees

Property 1 establishes that all paths are strip-drawable, since they are in fact 1-track drawable. We define a tree as 2-strict if it contains a vertex of degree greater than or equal to three. An immediate consequence of Property 1 is the following.

Property 3 A 2-strict tree is not 1-track drawable.

An edge is defined as a core edge if its removal results in two 2-strict components. For an edge $e = (u, v)$, we refer to the two subtrees resulting from its removal (but including vertices $u$, $v$) as $T_u$ and $T_x$.

Lemma 1 Core edges are connected.

![Core edges are connected](image)

Figure 6: Core edges are connected

Proof. Let $e_1 = (u, v)$ and $e_2 = (w, x)$ be two core edges and consider any edge $e$ on the path connecting $e_1$ to $e_2$. Refer to Figure 6. Edge $e$ receives one 2-strict component from $T_u$ and one from $T_x$ and thus must be core.

Lemma 2 A tree is strip drawable if and only if its core edges form a path.

Proof. ($\Rightarrow$) (by contradiction) By the previous lemma, if the core edges do not form a path, then there is a vertex $v$ with at least three incident core edges $(v, a), (v, b), (v, c)$ see Figure 7. If the subtrees $T_u, T_b, T_c$ are drawable then by Property 3 their associated drawings $\Gamma_u, \Gamma_b, \Gamma_c$ each require two tracks. There is no location for $v$ that permits a crossing-free connection to all three subdrawings. ($\Leftarrow$) Refer to Figure 8. If the core edges form a non-degenerate path (i.e. a non-zero length path), then draw them consecutively on track $t_1$. Consider an arbitrary non-core edge $e = (u, v)$ with $u$ on track $t_1$. Since $e$ is non-core, $T_v$ must not be 2-strict and is thus 1-track drawable. Therefore $v$ can be placed on track $t_2$ with the drawing of $T_v$ also on the same track, as in Figure 8. There is one degenerate case to consider. If there are no core edges (i.e. a path of length 0), then either the tree has no vertex of degree three and is in fact drawable on a single track, or there exists at most one vertex $v$ with neighbours $w_1, w_2, ..., w_k$ and each $T_{w_i}$ is not 2-strict. Each of the subtrees can
Figure 7: T is not strip-drawable if the core edges are not a path

Figure 8: Drawing a tree on a strip

thus be drawn on track $t_2$ and $v$ on track $t_1$ as in Figure 9.

Based on this characterization, we now consider the complexity of recognizing and drawing the trees that are strip-drawable.

**Lemma 3** Let $T$ be a tree with $n$ vertices. There exists an $O(n)$-time algorithm that recognizes whether $T$ is strip-drawable and, if so, computes a strip drawing of $T$.

**Proof.** Note that a tree is 2-strict if and only if it has more than two leaves; thus counting leaves is the crucial operation. First the core edges must be

Figure 9: A degenerate core path
established and then the path condition on the core edges checked. With each edge $e = (u, v)$ we associate two counters: $l_u$ will be the number of leaves in $T_u$, and $l_v$ will be the number of leaves in $T_v$. Let $l$ be the number of leaves in the entire tree $T$. Since $l_u + l_v = l$ it follows that $e$ is a core edge if and only if both $l_u$ and $l_v$ are larger than 2. Choose an arbitrary non-leaf vertex $r$ as a root. Each vertex $v$ reports the number of leaves in the subtree below it to its parent $u$ thus establishing $l_v$ for the edge $(u, v)$ and hence $l_u$. If $v$ has no children then it is a leaf and reports 1. A simple recursive function can be used to implement this counting step in linear time. Finally, checking that the core edges form a path is easily accomplished in linear time and the proof of the previous Lemma described the construction of the strip drawing.

We can summarize Lemmas 2 and 3 as follows.

**Theorem 3** A tree $T$ with $n$ vertices is strip drawable if and only if its core edges form a path. Furthermore, there exists an $O(n)$-time algorithm that determines whether $T$ is strip drawable and, if so computes a strip drawing of $T$.

### 3.2.2 $k$-Strict Trees

![3-strict tree](image)

Figure 10: A 3-strict tree

The results of Theorem 3 can be extended to give a necessary condition for trees to be drawable on an $n \times k$ grid by generalizing the concepts of the previous section. A tree is $k$-strict if it contains a vertex adjacent to at least three vertices whose subtrees are $(k - 1)$-strict. For example, the tree of Figure 10 is 3-strict since the vertex $u$ is adjacent to three 2-strict subtrees.

**Lemma 4** A $(k + 1)$-strict tree is not drawable on an $n \times k$ grid.

**Proof.** The proof is by induction on $k$ and Property 3 provides the base case. If a tree $T$ is $(k + 1)$-strict then it contains a vertex $v$ adjacent to at least three vertices whose subtrees are $k$-strict and by the inductive hypothesis each subtree requires at least $k$ tracks to be drawn. In this case, there is no location for $v$ on the $k$ tracks that allows it to connect to the three subtrees without creating an intersection.
Corollary 1 The complete ternary tree of height \( k + 1 \) is not drawable on an \( n \times k \) grid.

Proof. Such a tree is \((k + 1)\)-strict and hence not drawable on the \( n \times k \) grid.

\[ \square \]

3.2.3 \( k \)-strict trees and Path-width

In this subsection we show that the strictness of a tree is tightly related to the well known parameter path-width.

Theorem 4 Let \( T \) be a tree. Then

\[ \text{pw}(T) \leq \max_k (T \text{ is } k\text{-strict}) \leq \text{pw}(T) + 1. \]

Proof. For the proof we compare the strictness of a tree \( T \) to its node search number \( ns(T) = \text{pw}(T) + 1 \) (refer to the beginning of this section for the definitions). In the proof we make use of a lemma attributed to Parsons [32] in [29]

[Parsons’ Lemma] For any tree \( T \) and integer \( k \geq 1 \), \( ns(T) \geq k + 1 \) if and only if \( T \) has a vertex \( v \) at which there are three or more branches that have search number \( k \) or more.

First we show that for a tree \( T \) \( k \)-strictness implies \( ns(T) \geq k \), by induction on \( k \). Assume \( T \) is 2-strict. Then \( T \) contains a vertex of degree 3; in particular therefore at least one edge and \( ns(T) \geq 2 \). Now assume \( T \) is \( k\)-strict, \( k > 2 \). Then \( T \) contains a vertex \( v \) at which three branches \( T_1, T_2, T_3 \) are \((k - 1)\)-strict. By induction, each \( T_i \) satisfies \( ns(T_i) \geq k - 1 \), and by Parsons’ lemma \( ns(T) \geq k \).

Next we show that \( ns(T) \geq k \) implies that \( T \) is \((k - 1)\)-strict, again by induction on \( k \). Assume that \( ns(T) = 2 \). Then \( T \) contains an edge, and therefore it is 1-strict. Now \( ns(T) = k > 2 \). By Parsons’ lemma \( T \) contains a vertex \( v \) with three branches \( T_1, T_2, T_3 \) such that \( ns(T_i) \geq k - 1 \). By induction, \( T_i \) is \((k - 2)\)-strict, and therefore \( T \) is \((k - 1)\)-strict.

\[ \square \]

4 Three-Dimensional Drawings of Outerplanar Graphs

In Section 3, Corollary 1 showed that, for a fixed \( k \), there is no \( n \times k \) grid that supports all trees of \( n \) vertices. This motivates us to investigate the existence of three-dimensional restricted grids that support all trees. As it turns out, the situation in three dimensions is distinctly different. Namely, we show that all outerplanar graphs are prism-drawable by providing a linear time algorithm
that computes this drawing. This is the first known three-dimensional straight-line drawing algorithm for the class of outerplanar graphs that achieves $O(n)$ volume on an integer grid. A high level description of our drawing algorithm, called Algorithm Prism Draw, is as follows. Let $G$ be an outerplanar graph with a specified outerplanar embedding, i.e., a circular ordering of the edges incident around each vertex such that all vertices of $G$ belong to the external face. (Such an embedding can be computed in linear time). Algorithm Prism Draw computes a prism drawing of $G$ by executing two main steps. Firstly a 2D drawing of $G$ is computed on a grid that consists of $O(n)$ horizontal tracks and such that adjacent vertices are at grid points whose $y$-coordinates differ by at most one. This is done by visiting $G$ in a breadth-first fashion and setting the $x$-coordinate to be the breadth-first search (BFS) number and the $y$-coordinate to be the depth in the BFS tree. Secondly, the drawing is “wrapped” onto the faces of a prism by folding it along the tracks.

![Figure 11: An outerplanar graph drawn by Step 1 of Algorithm Prism Draw.](image)

**Algorithm Prism Draw**

**input:** An outerplanar graph $G$ with a given outerplanar embedding.

**output:** A prism drawing of $G$.

**Step 1.** The 2D Drawing Phase: A 2D track drawing $\Gamma$ of $G$ where vertices are assigned to different $x$-coordinates is computed as follows.

- Add a dummy vertex $d$ on the external face and an edge connecting $d$ to an arbitrary vertex $v$.
- mark $d$
- $i := 0$
- $currx := 0$
- draw $v$ on track $t_0$ by setting $X(v) := currx, Y(v) := i$
- $currx := currx + 1$
- mark $v$
• while there are unmarked vertices of $G$ do
  visit the vertices on track $t_i$ from left to right and for each encountered vertex $u$ do
  * let $w$ be a marked neighbour of $u$ in $G$
  * visit the neighbours of $u$ in counterclockwise order starting from $w$, and for each encountered vertex $r$ such that $r$ is unmarked do
    • draw $r$ on track $t_{i+1}$ by setting $X(r) := currx; Y(r) := i+1$
    • $currx := currx + 1$
    • mark $r$
    • $i := i+1$

Step 2: The 3D Wrapping Phase: A prism drawing $\Gamma'$ is obtained by folding $\Gamma$ along its tracks as follows.

• for each vertex $v$ of $\Gamma$ define its coordinates $X'(v), Y'(v)$ and $Z'(v)$ in $\Gamma'$ by setting:
  \[
  X'(v) := X(v)
  \]
  if $Y(v) = 0, 1 \mod 3$ then $Y'(v) := 0$, else $Y'(v) := 1$
  if $Y(v) = 0, 2 \mod 3$ then $Z'(v) := 0$, else $Z'(v) := 1$

End of Algorithm Prism Draw

Figure 11 shows an example of the output of Step 1 of the algorithm; for consistency with track layout terminology, the $Y$ axis points downwards. The following results establish that Algorithm Prism Draw computes a prism drawing of any outerplanar graph $G$. First observe that $currx$ is incremented each time a vertex is drawn, and therefore we have the following proposition.

**Proposition 1** No two vertices of $\Gamma$ are assigned the same $X$-coordinate.

Also, since the unmarked neighbours of a vertex $u$ are all drawn on the track consecutive to that of $u$ during Step 1, we have the following.

**Proposition 2** A vertex is assigned to track $t_{i+1}$ if and only if it has not yet been marked/assigned and has a neighbour on track $t_i$, for $i \geq 0$.

The following lemmas establish that the drawing between any two consecutive tracks forms a strip drawing, and therefore Step 1 of Algorithm Prism Draw computes a $k$-track drawing of the input graph.

**Lemma 5** Let $G$ be an outerplanar graph with a given embedding and let $\Gamma$ be the drawing computed by Step 1 of Algorithm Prism Draw. Then $\Gamma$ is a $k$-track drawing of $G$ for some $k \leq n$. 

Figure 12: Two cases for the proof of Lemma 5.

Proof. Step 1 of Algorithm Prism Draw draws $G$ on a 2D $k$-track, where $k \leq n$. Also, by Proposition 2 we have that an edge of $\Gamma$ can connect only vertices that are drawn either on the same track or on two consecutive tracks. In order to complete the proof we must show that $\Gamma$ satisfies the following properties.

1. No two edges connecting vertices on consecutive tracks intersect.

2. Let $u$ and $v$ be two vertices of $\Gamma$ which are drawn on the same track $t$. If $u$ and $v$ are adjacent in $G$, then they appear consecutively on $t$.

We start by proving that $\Gamma$ has the first property. Suppose there exist four vertices $a, b, c, d$ such that
- $a$ and $b$ are on track $t_i$ and $a$ is to the left of $b$.
- $c$ and $d$ are on track $t_{i+1}$.
- There is an edge $(a, d)$ intersecting an edge $(b, c)$.

Note that Algorithm Prism Draw draws all the unmarked neighbours of $a$ on track $t_{i+1}$ by following the counterclockwise order of the edges around $a$ given by the outerplanar embedding of $G$. Also note that all the neighbours of $a$ on track $t_{i+1}$ are assigned an $X$-coordinate that is strictly smaller than the $X$-coordinates assigned to the neighbours of any vertex drawn to the right of $a$ on track $t_i$. Therefore we may conclude that if $(a, d)$ and $(b, c)$ cross, then one of the two cases must hold: Case 1: Vertex $c$ is a neighbour of both $b$ and $a$ (see Figure 12a). Case 2: There is a vertex $x$, drawn on track $t_i$ to the left of $a$ and such that $c$ is a neighbour of both $x$ and $b$ (see Figure 12b). Consider Case 1. By Proposition 2 and by the fact that Algorithm Prism Draw places only vertex $v$ on track $t_0$, it follows that there exists a lowest common ancestor of both $a$ and $b$, say $w$, drawn on some track $t_j$ with $0 \leq j < i$. Let $\Pi_{wa}$ and $\Pi_{wb}$, be two disjoint paths connecting $w$ to $a$ and $w$ to $b$ respectively. Observe that Step 1 of Algorithm Prism Draw computes a drawing that preserves the given outerplanar embedding of $G$ since it draws the vertices on consecutive tracks with
increasing $x$ values and by following the circular ordering of the edges around the vertices. Therefore, if edge $(a, d)$ follows edge $(a, c)$ in the counterclockwise ordering of the edges around $a$, then in the outerplanar embedding of $G$ there must be a cycle (namely that formed by the path $\Pi_{w,a}$, edge $(a, c)$, edge $(c, b)$ and path $\Pi_{ub}$) with vertex $d$ in its interior. But this is a contradiction. Now consider Case 2. By the same argument used for the previous case, there is a lowest common ancestor $w$ of $x$ and $b$ on some track $t_j$ with $0 \leq j < i$. Let $\Pi_{wx}$ and $\Pi_{ub}$ be two disjoint paths connecting $w$ to $x$ and $w$ to $b$ respectively. Now observe that vertex $d$ would necessarily lie in the interior of the cycle defined by $\Pi_{wx}$, edge $(x, c)$, edge $(c, b)$ and path $\Pi_{ub}$ thus contradicting the fact that $\Gamma$ preserves the outerplanar embedding of $G$. Finally, we prove that $\Gamma$ satisfies the

![Diagram](image)

Figure 13: Edges on a given track only join consecutive vertices.

second property and again the proof is by contradiction. Suppose there exist two vertices $a$ and $b$ on track $t_i$ ($0 < i \leq k$) such that:

- $a$ and $b$ are adjacent in $G$.
- There exists a vertex $c$ in $\Gamma$ such that $c$ is drawn on track $t_i$ between $a$ and $b$. See also Figure 13.

By the same reasoning as that used in the previous cases, let $w$ be the lowest common ancestor of $a$ and $b$ on some track $t_j$ with $0 \leq j < i$ and let $\Pi_{wa}$ and $\Pi_{wb}$ be two disjoint paths connecting $w$ to $a$ and $w$ to $b$ respectively. Consider the cycle formed by $\Pi_{wa}$, $\Pi_{wb}$ and edge $(a, b)$. This cycle has vertex $c$ in its interior contradicting the fact that $\Gamma$ preserves the outerplanar embedding of $G$.

**Theorem 5** Every outerplanar graph $G$ with $n$ vertices admits a crossing-free straight-line grid drawing in three dimensions in optimal $O(n)$ volume. Furthermore, Algorithm Prism Draw computes such a drawing of $G$ in $O(n)$ time and with the vertices of $G$ drawn on the grid points of a prism.

**Proof.** Lemma 5 ensures there are no crossings in the $k$-track drawing. Concerning Step 2 (3D Wrapping Phase), observe that the coordinate assignment is such that the vertices of $\Gamma'$ are grid points of a $n \times 2 \times 2$ grid and they all belong to just three of the four possible tracks of the $n \times 2 \times 2$ grid. Therefore,
the vertices of $\Gamma'$ are drawn on grid points of a prism. Also, no two edges of $\Gamma'$ intersect because, as shown above, each subdrawing of $\Gamma'$ induced by vertices on two different tracks is a strip drawing and because the vertices on each track have distinct X-coordinates. Finally, note that Algorithm Prism Draw runs in linear time since it is essentially a breadth-first traversal of the graph. \hfill \Box

Remark: Note that Step 2 of the algorithm is applicable given any track-drawing of a graph after suitable shifting to ensure increasing x-coordinates. Thus, graph $G$ is track-drawable implies that $G$ is prism-drawable. The converse however does not hold; $K_4$ is an example of a graph that is prism-drawable but not track-drawable.

5 Prism-Drawable Graphs

Motivated by Theorem 5, we study in this section whether the prism is a universal grid for planar graphs. For example, Figure 14 shows a maximal planar graph, and its prism drawing. As another example, note that the family of maximal planar graphs consisting of a sequence of nested triangles (as in Figure 2) and that are known to require $\Omega(n^2)$ area in the plane [11], can easily be drawn on the prism in $O(n)$ volume. Unfortunately, it turns out that not all planar graphs are prism-drawable. In Section 5.1 we give a characterization of prism-drawable graphs and in Sections 5.2 and 5.3 we illustrate two different approaches for constructing planar graphs that violate the characterization. The first approach is based on the concept of strictly-prism drawable graphs and the second exploits the relationship between hamiltonicity and prism-drawability.

5.1 Characterization of Prism-Drawable Graphs

An essential prerequisite of our characterization of prism-drawable graphs, is the study of the strip-drawable graphs since a prism effectively consists of three
 strips. Independently, Cornelsen, Schank and Wagner [10] developed a linear-time algorithm for determining if a graph is strip-drawable. Clearly such graphs must be (a subset of the) outerplanar graphs since the two tracks, which contain all vertices, form the exterior face. Our characterization differs significantly from that contained in [10].

We define a spine in a graph \( G \) as a sequence \( v_0, v_1, \ldots, v_n \) of vertices such that the subgraph induced by \( v_0, v_1, \ldots, v_n \) is a path. The definition of spine precludes any edge between non-consecutive vertices; we refer to such an edge as a chordal edge. The characterization of prism-drawable graphs is based on the observation that in a strip drawing, there must exist two sub-spines (each defined by the vertices on one of the two tracks of the strip) and that edges connecting vertices on these two sub-spines must not intersect. Since every graph with less than four vertices is clearly strip-drawable (a three cycle is strip-drawable and therefore every subgraph of a three cycle is strip-drawable), the next theorem considers graphs with at least four vertices. Note that although this characterization is not efficiently implementable, it is a basis for characterizing the prism-drawable graphs, the box-drawable graphs and provides a means for showing that planar graphs are not necessarily prism-drawable.

**Theorem 6** A graph \( G \) with at least four vertices is strip-drawable if and only if it is possible to augment \( G \) with edges to produce a graph \( G' \) such that:

- \( G' \) contains two edges \((r_0, b_0)\) and \((r_z, b_t)\).
- There are two vertex-disjoint spines \( r_0, r_1, \ldots, r_z \) and \( b_0, b_1, \ldots, b_t \) in \( G' \) such that all vertices of \( G \) are on the two spines.
- If there exists an edge \((r_i, b_j)\) with \( 0 \leq i \leq z \) and \( 0 \leq j \leq t \) then there are no edges of the form \((r_k, b_l)\) with \( 0 \leq k < i \) and \( j < l \leq t \) or \( i < k \leq z \) and \( 0 \leq l < j \).

**Proof.** \((\Rightarrow)\) We show how to construct a graph \( G' \) that satisfies the statement. Let \( \Gamma \) be a strip drawing of \( G \) with \( t_1 \) and \( t_2 \) as the two tracks of the strip. Let \( r_0, b_0 \) be the leftmost pair of vertices and let \( r_z, b_t \) be the rightmost pair of vertices of \( \Gamma \) such that \( b_0 \) and \( b_t \) are on track \( t_1 \). If \( r_0, b_t \) are not adjacent in \( \Gamma \), then edge \((r_0, b_t)\) is added; similarly, if \( r_i, b_t \) are not adjacent in \( \Gamma \), then edge \((r_i, b_t)\) is added. Also, for each pair of consecutive non-adjacent vertices encountered when walking along each track an edge is added so to form two paths \( \Pi_1 \) and \( \Pi_2 \). Let \( \Gamma' \) be the new drawing and let \( G' \) be the graph represented by \( \Gamma' \). Note that \( G' \) has two edges \((r_0, b_0)\) and \((r_z, b_t)\). Since there are no chordal edges between any two non-consecutive vertices of \( \Gamma \) that are on the same track, it follows from the construction that \( \Pi_1 \) and \( \Pi_2 \) are spines for \( G' \). Each vertex of \( G \) is drawn either on track \( t_1 \) or on track \( t_2 \) and by construction of \( \Gamma' \) it belongs either to \( \Pi_1 \) or to \( \Pi_2 \); it follows that all vertices of \( G \) are on the two spines of \( G' \). Also, since in \( \Gamma \) there are no crossings between any two edges connecting vertices on different tracks and since in \( \Gamma' \) edges \((r_0, b_0)\) and \((r_z, b_t)\) do not cross any other edge, it follows that if there exists an edge \((r_i, b_j)\) in \( G' \) with \( 0 \leq i \leq z \)
and \(0 \leq j \leq t\) then there cannot be edges of the form \((r_k, b_i)\) with \((0 \leq k < i\) and \(j < l \leq t\)) or \((i < k \leq z\) and \(0 \leq l < j\)).

(\(\Rightarrow\)) Given an augmented graph \(G'\), a strip drawing \(\Gamma'\) of \(G'\) is obtained as follows. Spine \(r_0, r_1, \ldots, r_z\) is drawn on one track such that \(r_j\) is drawn to the right of \(r_i\) for \(0 \leq i < j \leq z\). Spine \(b_0, b_1, \ldots , b_t\) is drawn on the second track such that \(b_j\) is drawn to the right of \(b_i\) for \(0 \leq i < j \leq t\). Edges connecting vertices along the same track and between the two tracks are drawn as straight-line segments. Since the subgraph induced by each spine is a path and since for each edge \((r_i, b_j)\) with \(0 \leq i \leq z\) and \(0 \leq j \leq t\) there are no edges of the form \((r_k, b_i)\) with \(0 \leq k < i\) and \(j < l \leq t\) or \((i < k \leq z\) and \(0 \leq l < j\)), it follows that the drawing of \(G'\) does not have crossings. Finally, a strip drawing of \(G\) is obtained by deleting edges from \(\Gamma'\).

The characterization of prism drawable graphs generalizes Theorem 6 to three dimensions. Intuitively, it must be possible to augment a given graph to obtain three spines with two “lids” (three cycles) and between each pair of spines the strip drawability condition must hold. Since every strip-drawable graph is also prism-drawable, the next theorem assumes that \(G\) has at least four vertices.

**Theorem 7** A graph \(G\) with at least four vertices is prism-drawable if and only if it is possible to augment \(G\) with edges to produce a graph \(G'\) such that:

- \(G'\) contains two three-cycles \(r_0, b_0, g_0\) and \(r_z, b_t, g_s\), where \(z, t, s \geq 0\).
- There are three vertex-disjoint spines \(r_0, r_1, \ldots, r_z, b_0, b_1, \ldots, b_t, g_0, g_1, \ldots, g_s\) in \(G'\) such that all vertices of \(G\) are on the three spines.
- For each pair of spines \(x_0, x_1, \ldots, x_m\) and \(y_0, y_1, \ldots, y_p\) \((x, y \in \{r, b, g\}, x \neq y, m, p \in \{z, t, s\})\), if \((x_i, y_j)\) is an edge, then there are no edges of the form \((x_k, y_i)\) with \(0 \leq k < i\) and \(j < l \leq p\) or \((i < k \leq m\) and \(0 \leq l < j\)).

**Proof.** (\(\Rightarrow\)) We show how to construct a graph \(G'\) that satisfies the statement. Let \(\Gamma\) be a prism drawing of \(G\) and let \(t_1, t_2, t_3\) be the three tracks of the prism. Consider the subgraph \(G_{ij}\) induced by the vertices that are on two different tracks \(t_i\) and \(t_j\) \((i, j = 1, 2, 3, i \neq j)\); \(G_{ij}\) is strip-drawable and therefore there exists an augmented graph \(G'_{ij}\) with the properties stated by Theorem 6.

A graph \(G'\) that satisfies the statement is then defined as \(G' = G'_{12} \cup G'_{13} \cup G'_{23}\).

(\(\Rightarrow\)) Given an augmented graph \(G'\), a prism drawing \(\Gamma'\) of \(G'\) is obtained as follows. Spine \(r_0, r_1, \ldots, r_z\) is drawn on track \(t_1\) such that \(r_j\) is drawn to the right of \(r_i\) for \(0 \leq i < j \leq z\). Spine \(b_0, b_1, \ldots, b_t\) is drawn on track \(t_2\) such that \(b_j\) is drawn to the right of \(b_i\) for \(0 \leq i < j \leq t\). Spine \(g_0, g_1, \ldots, g_s\) is drawn on track \(t_3\) such that \(g_j\) is drawn to the right of \(g_i\) for \(0 \leq i < j \leq s\). Edges connecting vertices along the same track and between the two different tracks are drawn as straight-line segments. Since the subgraph induced by each spine is a path and since for each edge \((x_i, y_j)\) \((x, y \in \{r, b, g\}, x \neq y; m, p \in \{z, t, s\})\) there are no edges of the form \((x_k, y_i)\) with \(0 \leq k < i\) and \(j < l \leq p\) or \(i < k \leq m\) and
0 ≤ l < j, it follows that \( \Gamma' \) does not have crossings. Finally, a prism drawing of \( G \) is obtained by deleting edges from \( \Gamma' \).

In the rest of the paper it will be convenient to imagine the three spines \( r_0, r_1, \ldots, r_z, b_0, b_1, \ldots, b_t \), and \( g_0, g_1, \ldots, g_4 \) of Theorem 7 as coloured red, blue and green, respectively. Also, we shall refer to a graph \( G' \) described in Theorem 7 as an \textit{augmented graph} of \( G \).

### 5.2 Prism-Drawability and Planarity

In this section we show that prism drawable graphs are a proper subset of planar graphs. In the next section we shall further restrict the set of prism-drawable graphs.

**Theorem 8** Let \( G \) be a prism-drawable graph. Then \( G \) is planar.

**Proof.** Any prism-drawing of \( G \) can be augmented by edges to form a convex polytope and therefore by the theorem of Steinitz [43] only planar graphs are prism-drawable.

**Corollary 2** If \( G \) is a maximal planar graph and is prism drawable, then the augmented graph \( G' \) coincides with \( G \).

One approach for constructing planar \textit{prism-forbidden} graphs, \textit{i.e.} planar graphs which do not admit a prism drawing, is based on the following definition and lemma. A graph \( G \) is \textit{strictly prism-drawable} if it is prism-drawable and all prism drawings of \( G \) have at least three edges \( (x, y), (y, z) \) and \( (z, x) \) such that \( x, y \) and \( z \) are on different tracks.

**Lemma 6** Let \( G \) be a 1-connected planar graph that has a cut vertex \( v \) whose removal separates the graph into \( h \) strictly prism-drawable components \( G_1, \ldots, G_h \) \( (h \geq 3) \). Then \( G \) is prism-forbidden.

![Figure 15: The “slicing” argument in the proof of Lemma 6.](image)
is strictly prism-drawable. Thus, $\Gamma_1, \ldots, \Gamma_h$ slice the prism into $h+1$ slices (see Figure 15). Now there is no location for $v$ that permits it to be connected to all $\Gamma_i$ ($0 \leq i \leq h$) without crossing at least one three-cycle.

![Figure 16: A strictly prism-drawable graph.](image)

Lemma 6, provides the key to creating a prism-forbidden graph. Although $K_4$ can easily be shown to be strictly prism-drawable we choose to show that the graph in Figure 16 is strictly prism-drawable for three reasons: the extension to the box-forbidden case is more natural, the series-parallel case follows as a consequence, and the proof portrays the importance of the spine characterization of Theorem 7.

**Lemma 7** The graph in Figure 16 is strictly prism-drawable.

**Proof.** Let $G$ be the graph of Figure 16. We first show that $G$ satisfies Theorem 7. The augmented graph $G'$ is defined by adding to $G$ edges $(a, b)$ and $(b, c)$. We choose the two three-cycles of $G'$ as follows: One three-cycle consists of edges $(u, v), (v, a), (a, u)$; the second three-cycle consists of edges $(u, v), (a, c), (c, v)$. The three spines of $G'$ are as follows: the red spine is the path of vertices $a, b, c$, the blue spine consists of vertex $u$ and the green spine consists of vertex $v$. Since $G'$ is planar and two of the three spines consist of a single vertex, the non-crossing condition stated by Theorem 7 among edges connecting vertices on different spines is trivially verified. It follows that $G$ is prism-drawable. It remains to show that $G$ is strictly prism-drawable. This is done by proving the following two claims.

1. In any prism drawing of $G$ vertices $u$ and $v$ cannot be on the same track.

2. In any prism drawing of $G$ at least one of vertices $a, b, c$ is drawn on a track different from that of $u$ and different from that of $v$.

To prove Claim 1, suppose that there existed a prism drawing $\Gamma$ of $G$ with $u$ and $v$ on the same track $t_1$ (see Figure 17(a)). Since $u$ and $v$ are adjacent in $G$, there exists in $\Gamma$ a straight-line segment connecting $u$ to $v$. As a consequence neither $a, b, c$ can be drawn on $t_1$ or else there would be an edge overlapping
edge \((u, v)\). It follows that vertices \(a, b,\) and \(c\) are drawn as points of the other two tracks, and therefore at least two of them are on the same track. Suppose without loss of generality that \(a\) and \(b\) are both drawn on track \(t_2\). Observe that there is no way of drawing edges \((a, u), (a, v), (b, u), (b, v)\) avoiding a crossing. It follows that in any prism drawing of \(G\) \(u\) and \(v\) must appear on different tracks.

To prove Claim 2 we assume that \(u\) is drawn on track \(t_1\) and that \(v\) is drawn on track \(t_2\). Let \(t_3\) be the third track of the prism. Assume there existed a prism drawing with vertices \(a, b,\) and \(c\) all on tracks \(t_1\) and \(t_2\). Assume without loss of generality that both \(a\) and \(b\) are on track \(t_1\). In order to avoid crossings it must be that one vertex, say \(a\), is on the right-hand side and the other is on the left-hand side of \(u\) (see Figure 17(b)). Note however that \(c\) cannot be drawn on track \(t_1\) or else edge \((u, c)\) would intersect one of the edges \((a, u), (b, u)\). But if \(c\) were drawn on track \(t_2\), then edge \((c, u)\) would intersect either \((a, v)\) or \((c, v)\). It follows that \(c\) is drawn on track \(t_3\) and therefore \(G\) is strictly prism-drawable.

\[\square\]

![Diagram](image)

Figure 17: Illustration for the proof of Lemma 7.

**Theorem 9** There exist prism-forbidden planar graphs.

**Proof.** Let \(G\) be a planar graph with a vertex \(v\) adjacent to three copies of the graph of Figure 15. Let \(G_0\) be the subgraph of \(G\) induced by \(v\) and by these three copies. By Lemma 6 \(G_0\) is prism-forbidden. It follows that also \(G\) is prism-forbidden. \(\square\)

A consequence of the previous lemmas is the following.

**Corollary 3** There exist prism-forbidden series-parallel graphs.

**Proof.** Let \(G\) be the graph in Figure 18. By using the same argument in the proof of Theorem 9 the corollary follows. \(\square\)
5.3 Prism-Drawability and Hamiltonicity

Theorem 9 shows that not all planar graphs admit a prism drawing. In this section, we further restrict the family of drawable graphs by exploiting the relation between prism-drawability and hamiltonicity.

A graph is subhamiltonian if it can be augmented with edges to produce a planar graph having a Hamiltonian cycle.

Lemma 8 Let $G$ be a prism-drawable graph. Then $G$ is subhamiltonian.

Proof. Let $\Gamma$ be a prism drawing of $G$ and let $G'$ be a maximally augmented graph obtained from $G$ by adding edges to satisfy the conditions of Theorem 7. Let the three tracks of the prism be labeled $t_1$, $t_2$ and $t_3$ (see for example Figure 19(a)). Label the vertices on track $t_2$, as $r_0, \ldots, r_z$ and the vertices on track $t_3$ as $b_0, \ldots, b_y$. The Hamiltonian cycle begins at the start vertex of $t_1$, visits the start vertex of $t_2$, $(r_0)$, the start vertex of $t_3$ $(b_0)$ and then alternates between the $t_2$ and $t_3$ track visiting all vertices on those two tracks and ending at the end vertex of either tracks $t_2$ or $t_3$ (see for example Figure 19(b)). In either case, the cycle then visits the end vertex of $t_1$ and then the entire $t_1$ spine in reverse order.

We now give a more formal description of the cycle’s traversal of the strip between tracks $t_2$ and $t_3$. Note that $r_0$ is adjacent to $b_0$ (and 0 or more consecutive vertices on track $t_3$). Since $G'$ is maximally augmented, each vertex $b_i$ ($0 < i < y$) is adjacent to $b_{i-1}$ and $b_{i+1}$ and to a non-empty set of consecutive vertices on the $r$-track $r_j, \ldots, r_{j+k}$. Furthermore, $r_j$ is adjacent to $b_{i-1}$, and $r_{j+k}$ is adjacent to $b_{i+1}$. The Hamiltonian cycle goes from $r_0$ to $b_0$ and then applies a greedy-like approach. In general, from $b_i$, the cycle goes to the first (i.e., lowest-indexed) neighbour $r_j$ that has not previously been visited. Only if all the neighbours of $b_i$ on the $r$-track have been visited, does the cycle go to $b_{i+1}$. The rule on the $r$ track is symmetric. Since at each vertex, there is always at least one neighbour that has not been visited, namely the next vertex on the same track, it is clear that the cycle can always proceed. To establish that all vertices are visited, a straightforward proof by contradiction can be applied.
The (partial) hamiltonian cycle thus ends at the endpoint of either track \( t_2 \) or \( t_3 \) and can be completed as described above.

![Diagram](image)

**Figure 19:** Illustration for the proof of Lemma 8

A natural question arising from Lemma 8 is whether all subhamiltonian planar graphs are prism drawable. This is not the case, for example the graph of Figure 18 is subhamiltonian but not prism drawable. The following lemma shows that even subhamiltonian graphs with only 9 vertices may not be prism drawable. In this instance it is the proof technique that is of primary interest.

**Lemma 9** The hamiltonian maximal planar graph \( G \) of Figure 20 is prism-forbidden.

**Proof.** Suppose for a contradiction that \( G \) were prism-drawable and let \( G' \) be the augmented graph of \( G \) described in Theorem 5.

Consider the vertex \( a \) of \( G \) displayed in Figure 20. We start by showing that vertex \( a \) must be an endvertex in one of the three spines of \( G' \).

Let \( \Gamma \) be a prism drawing of \( G \). Since \( G \) is maximal planar, by Corollary 2 it follows that \( G \) coincides with its augmented graph \( G' \) and that \( \Gamma \) is also a prism drawing of \( G' \). If \( a \) were not an endvertex of a spine, then the point representing \( a \) in \( \Gamma \) would be adjacent to two other points on the same track. But all neighbours of \( a \) are mutually adjacent in \( G \) and this would imply a chordal edge in \( \Gamma \), which is impossible.

By the same argument, also vertices \( b \) and \( c \) of \( G \) (see Figure 20) are endvertices of some spine in \( G' \).

By Theorem 5, the endvertices of the spines in \( G' \) belong to two three-cycles. Therefore, at least two vertices among \( a, b, \) and \( c \) must be connected in \( G' \). But
$G$ is identical to $G'$ by Corollary 2 and no pair of these vertices are adjacent in Figure 20. This provides the required contradiction and proves that $G$ is indeed prism-forbidden.

Based on Lemmas 8 and 9 we can summarize the discussion of this section as follows.

**Theorem 10** The family of prism-drawable graph is a proper subset of the family of subhamiltonian planar graphs.

## 6 Box-Drawable Graphs

Motivated by Theorems 9 and 10, we consider a restricted integer 3D grid consisting of four tracks, namely the box, and ask whether this grid supports all planar graphs. Clearly, the class of box-drawable graphs is larger than the class of prism-graphs: Every prism-drawable graph can be drawn on the box and it is easy to draw some non-planar graphs on a box. For example, Figure 21 shows a box drawing of $K_5$ and a box drawing of $K_{3,3}$. However we will show that even the box is not a universal grid for planar graphs.

![Box Drawing](image)
6.1 Characterization of Box-Drawable Graphs

We start our investigation by characterizing the family of box-drawable graphs with more than five vertices. Note that any graph with at most five vertices is box drawable and its box drawing can be obtained by deleting edges and vertices from the drawing of $K_5$ depicted in Figure 21. The next theorem follows the same pattern as Theorem 7.

**Theorem 11** A graph $G$ with at least six vertices is box-drawable if and only if it is possible to augment $G$ with edges to produce a graph $G'$ such that:

- $G'$ contains two four-cycles $r_0, b_0, g_0, w_0$ and $r_z, b_!, g_!, w_!$ where $z, t, s, q \geq 0$.

- The graph $G'$ contains four vertex-disjoint spines $r_0, r_1, \ldots, r_z, b_0, b_1, \ldots, b_t, g_0, g_1, \ldots, g_s$, and $w_0, w_1, \ldots, w_q$ such that all vertices of $G$ are on the four spines.

- For each pair of spines $x_0, x_1, \ldots, x_m$ and $y_0, y_1, \ldots, y_p$ ($x, y \in \{r, b, g, w\}$, $x \neq y$, $m, p \in \{z, t, s, q\}$), if $(x_i, y_j)$ is an edge, then there are no edges of the form $(x_k, y_l)$ with $(0 \leq k < i$ and $j < l \leq p)$ or $(i < k \leq m$ and $0 \leq l < j)$.

**Proof.** ($\Rightarrow$) We show how to construct a graph $G'$ that satisfies the statement. Let $\Gamma$ be a box drawing of $G$ and let $t_1, t_2, t_3$, and $t_4$ be the four tracks of the box. Consider the subgraph $G_{ij}$ induced by the vertices that are on two different tracks $t_i$ and $t_j$ $(i, j = 1, 2, 3, 4, i \neq j)$; $G_{ij}$ is strip-drawable and therefore there exists an augmented graph $G'_{ij}$ with the properties stated by Theorem 6. A graph $G'$ that satisfies the statement is then defined as $G' = G'_{12} \cup G'_{13} \cup G'_{14} \cup G'_{23} \cup G'_{24} \cup G'_{34}$.

($\Leftarrow$) Among the four tracks $t_1, t_2, t_3$, and $t_4$ of the box, we assume that the pairs $t_1, t_3$ and $t_2, t_4$ are diagonally opposite and that the four tracks are horizontal lines. Given an augmented graph $G'$, a box drawing $\Gamma'$ of $G'$ is constructed by spiralling the vertices on the four tracks as follows.

- Spine $r_0, r_1, \ldots, r_z$ is drawn on track $t_1$ such that $r_j$ is drawn to the right of $r_i$ for $0 \leq i < j \leq z$.

- Spine $b_0, b_1, \ldots, b_t$ is drawn on the diagonally opposite track $t_3$ such that $b_i$ is given an $x$-coordinate larger than the $x$-coordinate of $r_z$ and $b_j$ is drawn to the right of $b_i$ for $0 \leq i < j \leq t$.

- Spine $g_0, g_1, \ldots, g_s$ is drawn on track $t_2$ such that $g_0$ is given an $x$-coordinate larger than the $x$-coordinate of $b_t$ and $g_j$ is drawn to the right of $g_i$ for $0 \leq i < j \leq s$.

- Spine $w_0, w_1, \ldots, w_q$ is drawn on track $t_4$ such that $w_0$ is given an $x$-coordinate larger than the $x$-coordinate of $g_s$ and $w_j$ is drawn to the right of $w_i$ for $0 \leq i < j \leq q$.

Then, edges connecting vertices along the same track and between two different tracks are drawn as straight-line segments. In order to see that the computed drawing does not have edge crossings observe the following:

- There are no edges between non-consecutive vertices on the same track: For each spine, the subgraph of $G'$ induced by the spine is a path which is drawn sequentially on a track.

- For each pair of tracks $t_h, t_f$ ($h, f \in \{1, 2, 3, 4\}, h \neq f$) the edges connecting vertices on $t_h$ with vertices on $t_f$ do not cross with each other. Namely, for an edge $(x_i, y_i)$ connecting a vertex on $t_h$ with a vertex on $t_f$, there are no edges of the form $(x_k, y_f)$ with $(k < i$ and $j < l)$ or $(i < k$ and $l < j)$.

- For each pair of diagonally opposite edges $e_1, e_2$ such that $e_1$ connects a vertex on track $t_1$ with a vertex on track $t_3$ and $e_2$ connects a vertex on track $t_2$ with a vertex on track $t_4$ there are no crossings. By construction, the coordinates of the endpoints of $e_2$ are both strictly larger than those of the endpoints of $e_1$.

Since $\Gamma'$ is a box drawing and $G'$ is a supergraph of $G$, a box drawing of $G$ can be obtained by deleting edges from $\Gamma'$.

\section{Box-Drawability and Planarity}

We extend the approach of Section 5.2 to construct planar graphs that cannot be drawn on a box. We call these graphs box-forbidden. In order to construct a box-forbidden graph, we need a preliminary lemma.

\begin{lemma}
In any box drawing of the graph of Figure 22 vertices $u$ and $v$ are on different tracks.
\end{lemma}

\begin{proof}
Let $G$ be the graph of Figure 22. It is trivial to see that $G$ is prism-drawable and hence it is also box-drawable. Let $\Gamma'$ be a box drawing of $G$. Suppose for a contradiction that vertices $u$ and $v$ in $\Gamma'$ were represented as points of the same track $t_1$. Observe that no other vertex of $\Gamma'$ can be a point of $t_1$ or else there would be a crossing. Since $G$ has six vertices, a box consists of four tracks, and track $t_1$ cannot contain more than two vertices; it follows that at least two other vertices of $\Gamma'$ must be on another track, say $t_2$ of the box. But each vertex on $t_2$ is adjacent to both $u$ and $v$, which forces a crossing in $\Gamma'$; contradiction.
\end{proof}

A graph $G$ is strictly box-drawable if it is box-drawable and there are four mutually adjacent vertices $a$, $b$, $c$ and $d$ and in all box drawings of $G$, $a$, $b$, $c$ and $d$ appear on separate tracks.

\begin{lemma}
The graph of Figure 23(a) is strictly box-drawable.
\end{lemma}
Proof. Let $G$ be the graph of Figure 23(a). We first prove that $G$ is box-
drawable and then that it is strictly box-drawable. We adopt the notation of
Figure 23(a).

We apply Theorem 11 to $G$. The four spines of $G'$ are $r_0, \ldots, r_8, b_0, \ldots, b_4,$
$p_0, \ldots, p_8$, and $w_0, \ldots, w_4$. The two four-cycles have the vertices $r_0, b_0, p_0$ and
$r_8, b_4, p_8, w_4$. Also, as Figures 23(b), (c), (d), (e), (f), and (g) show, the sub-
graphs of $G'$ induced by vertices on two different spines are strip-drawable. It
follows that $G$ is box-drawable.

We now prove that $G$ is strictly box-drawable. Graph $G$ consists of six
copies of the graph in Figure 22. By Lemma 10 in any box drawing of $G$
vertices $r_0, g_4, b_4, w_4$ must be on four different tracks. Furthermore, those four
vertices are mutually adjacent. It follows that $G$ is strictly box-drawable. \hfill \Box

Theorem 12 There exist box-forbidden planar graphs.

Proof. Let $G$ be a planar graph with a vertex $v$ adjacent to three copies of the
graph of Figure 23. Let $G_0$ be the subgraph of $G$ induced by $v$ and by these
three copies; see also Figure 24. Removing $v$ and all its incident edges from
the graph $G_0$ splits it into three components that we name $G_1, G_2$, and $G_3$. In any
box drawing $\Gamma_i$ of $G_i$ ($0 \leq i \leq 3$) there are four mutually adjacent vertices on
four different tracks because by Lemma 11 $G_i$ is strictly box-drawable. Thus,
$\Gamma_1, \Gamma_2$, and $\Gamma_3$ slice the box into 4 slices and there is no location for $v$ that
permits it to be connected crossing-free to all $\Gamma_i$ ($0 \leq i \leq 3$). \hfill \Box

7 Conclusions and Open Problems

In this paper we showed that all outerplanar graphs can be drawn in linear
volume on a prism – a restriction of the three dimensional integer grid. Proofs
that certain classes of planar graphs are not prism-drawable nor box-drawable
Figure 23: (a) Graph $G$ for Lemma 11. (b) (e) The subgraphs of $G$ induced by vertices on two different spines are strip-drawable.
were also provided. Although the problem of finding a universal integer 3D grid of linear volume that supports crossing-free straight line drawings of all planar graphs is still far from being solved, the drawing techniques and characterization results of this paper may provide a critical starting point for attacking such an ambitious research programme. We believe that the results on the restricted 2D grid are not only useful preliminary results for the study in three dimensions, but they may also shed some new light on the problem of drawing trees in linear area on the plane. There remain several interesting problems and directions for further research. We conclude the paper by describing some of the more intriguing open problems.

1. Can all outerplanar graphs be drawn in linear area on a 2D integer grid? Does there exist a 2D universal grid set of linear area that supports all outerplanar graphs?

2. Characterize the graphs drawable on an $n \times k$ grid.

3. Can the strong algorithms for recognizing graphs of bounded pathwidth be applied to devise polynomial dynamic programming algorithms to decide $k$-track drawability for fixed $k$? Such an approach has been applied in [18] for the recognition of proper $k$-track drawability for fixed $k$. Also, Schank [36] gave a direct linear time algorithm for the task of recognizing 2-track drawable graphs.

4. Can all planar graphs be drawn in linear volume on a three-dimensional integer grid? Does there exist a 3D universal grid set of linear volume that supports all planar graphs?
5. The \textit{k-lines drawability problem}: A related problem posed by H. de Fraysseix [13] asks if all planar graphs can be drawn on \(k\) parallel lines that lie on the surface of a cylinder, for a fixed value of \(k\). Our results on box-drawability imply that \(k\) would have to be strictly greater than 4.

6. The \textit{aspect ratio problem}: Our results about linear volume come at the expense of aspect ratio. Is it possible to achieve both linear volume and \(o(n)\) aspect ratio for outerplanar graphs? We conjecture that it is in fact not possible in 2D to simultaneously attain linear area and \(O(1)\) aspect ratio for some classes of planar graphs.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{fig25.png}
\caption{A graph \(S_n\) with poor aspect ratio}
\end{figure}

\textbf{Conjecture 1} There is no fixed constant \(k\) for which the family of graphs \(S_n\) (in Figure 25) can be drawn in a 2D integer grid of size \(k\sqrt{n} \times \sqrt{n}\).

Note that the graph \(S_n\) can be drawn on an \(n \times 3\) grid (and hence in linear area but with linear aspect ratio). Recently this conjecture was verified and the result is reported in [1].
